Chapter 14

Gender encoding on hybrid nouns in Bosnian/Croatian/Serbian: Experimental evidence from ellipsis

In this paper, we report the results of an experimental study on the possibility of gender mismatches with ellipsis of a particular type of hybrid nouns in Bosnian / Croatian / Serbian (henceforth: BCS). Using agreement mismatches under NP ellipsis as a diagnostic for gender feature specification of hybrid nouns, we show that these nouns disallow agreement mismatches under NP ellipsis if natural gender (and a presupposition that it introduces) is present either in the antecedent or the ellipsis site. We argue that natural gender feature (masculine in our study) can optionally be present on the hybrid noun, and that its inclusion in ellipsis contexts leads to a violation of the standard identity requirement between the antecedent and the ellipsis site, namely Merchant’s (2001) e-givenness.

Keywords: gender features, ellipsis, agreement, mismatches

1 Introduction: Hybrid nouns in BCS

Hybrid nouns have been a challenge for theories of agreement and NP structure (see Corbett 1991; Wechsler & Zlatić 2003; Alsina & Arsenijević 2012b,a; Peset-
sky 2013; Kramer 2015; Landau 2016; Smith 2015; 2016; Arsenijević & Gračanin-Yuksek 2015; Despić 2017), as it seems that they can simultaneously bear two types of gender specification: (i) natural gender (reflecting the gender of the referent) and (ii) grammatical gender (assigned arbitrarily). In this paper, we focus only on the Class II hybrid nouns in BCS (ending in -a) which have grammatical feminine gender, but variable natural gender, which depends on the discourse referent.

Table 1: Some hybrid nouns in BCS

<table>
<thead>
<tr>
<th>-a</th>
<th>-ica</th>
<th>-(č)ina</th>
</tr>
</thead>
<tbody>
<tr>
<td>mušterija</td>
<td>varalica</td>
<td>junačina</td>
</tr>
<tr>
<td>budala</td>
<td>propalica</td>
<td>dobričina</td>
</tr>
<tr>
<td>sudija</td>
<td>pijanica</td>
<td>drugarčina</td>
</tr>
<tr>
<td>tužibaba</td>
<td>spavalica</td>
<td>lažovčina</td>
</tr>
</tbody>
</table>

For instance, with a masculine referent, the noun mušterija (‘customer’) can trigger either grammatical feminine (1a)/(1b) or natural masculine agreement (1c)/(1d) (subject to speaker variability).

(1)  

a. Milan nam je nov-a mušterija.
    Milan us is new-f customer
    ‘Milan is our new customer.’

b. Nov-a mušterija je kupila jaknu.
    new-f customer is bought.f jacket.
    ‘A new (male or female) customer bought a jacket.’

c. % Milan nam je nov-i mušterija.
    Milan us is new-m customer
    ‘Milan is our new customer.’

d. % Nov-i mušterija je kupio jaknu.
    new-m customer is bought.m jacket.
    ‘A new (male) customer bought a jacket.’

With female referents, however, such nouns can only trigger feminine agreement:

(2)  

Marija nam je nov-a / *nov-i mušterija.
    Marija us is new-f new-m customer
    ‘Marija is our new customer.’
One could treat these as so-called “epicene” nouns of the type found e.g. in Brazilian Portuguese and Greek, which can be used with both masculine and feminine referents without change in form (Bobaljik & Zocca 2011; Merchant 2014; Kramer 2015). It has been proposed that such nouns are simply listed in the lexicon twice, each with a different gender feature (e.g. Merchant 2014: 19). However, such an approach to BCS hybrid nouns seems to be problematic, as there is evidence that these nouns can **simultaneously** bear natural and grammatical gender. For example, in (3) the adjective and determiner target different gender values of the noun, while (4) shows the same for the nominal modifier and the participle.\(^1\)

\[(3)\] ov-i \[ privatn-e \] zanatlije
\[ these-[M.PL] \] \[ private-[F.PL] \] artisan.PL
\[ ‘these private artisans’ \] (Corbett 2006: 206)

\[(4)\] Osm-a \[ budala \] je bio-∅ mnogo kul tip ali su ga se
eighth-[F.SG] fool.SG \[ is been-[M.SG] \] very cool guy but are him refl
drugi \[ malo \] plašili.\(^2\)
others little feared
‘The eighth fool was a very cool guy, but others were a bit afraid of him.’

These examples raise the question about the structural representation of such nouns: whether they do contain both types of gender feature simultaneously, and how exactly they should be represented. In what follows, we will answer these questions by using NP ellipsis as a diagnostic for the gender feature specification of BCS hybrid nouns.

\(^1\)Relative pronouns can also show different gender values than the attributive modifiers of a hybrid noun, as shown in (i), obtained at http://vukajlija.com/seoski-fudbalski-tim-iz-betonnige <accessed 26.11.2016>.

\[(i)\] Lokaln-a pijanica, koj-i je završio sa igranjem fudbala…
local-[F.SG] drunkard, who-[M.SG] is finished.M.SG \[ with playing \] football
‘A local drunkard, who’s finished playing football…’

However, as pointed out by a reviewer, whether the relative pronoun agrees directly with the hybrid noun, or whether agreement is more indirect (since we are dealing with a non-restrictive relative clause in which the relative pronoun is more akin to regular pronouns, c.f. de Vries 2006) is an issue that requires further investigation. See Arsenijević & Gračanin-Yuksek (2015) for further discussion on hybrid agreement with relative pronouns.

Andrew Murphy, Zorica Puškar & Matías Guzmán Naranjo

2 Gender mismatches and NP ellipsis

There is a growing body of literature on the permissibility of gender mismatches under NP ellipsis (e.g. Nunes & Zocca 2010; Bobaljik & Zocca 2011; Merchant 2014; Sudo & Spathas 2016; Barrie 2016). Based on whether gender mismatches under NP ellipsis are allowed or not, previous literature has identified three classes of nouns. The first type are the two-way alternating nouns (henceforth: the doctor-class), where a masculine antecedent can license deletion of a noun with a feminine referent, and vice versa:

(5) Two-way alternating nouns (doctor-class)
   a. O the Petros ine kalos jatros, ala i Maria ine mia kakia (jatros).
      the Petros is good.M doctor but the Maria is a.F bad.F doctor
      ‘Petros is a good doctor, but Maria is a bad one.’
   b. I the Maria ine kali jatros, ala o Petros ine enas kakos (jatros).
      the Maria is good.F doctor but the Petros is a.M bad.M doctor
      ‘Maria is a good doctor, but Petros is a bad one.’

   (Greek; Merchant 2014: 15)

The second type are the non-alternating nouns (henceforth: brother-class), which do not allow mismatches in either direction:

(6) Non-alternating nouns (brother-class)
   a. *O the Petros ine kalos adherfos, ala i Maria ine mia kakia
      the Petros is good.M brother but the Maria is a.F bad.F (adherfi).
      sister
      Intended: ‘Petros is a good brother, but Maria is a bad one (sister).’
   b. *I the Maria ine kali adherfi, ala o Petros ine enes kakos
      the Maria is good.F sister but the Petros is a.M bad.M (adherfos).
      brother
      Intended: ‘Petros is a good brother, but Maria is a bad one (sister).’

   (Greek; Merchant 2014: 12)

Finally, one-way alternating nouns (or the actor-class) allow a masculine noun to antecede an elided feminine noun (7a), but a mismatch in the opposite direction is ungrammatical (7b).
One-way alternating nouns (actor-class)

a. Ô Paulo é ator e a Fernanda também é ⟨atriz⟩.
   the Paulo is actor and the Fernanda also is actress
   ‘Paulo is an actor and Fernanda is too.’

b. * A Fernanda é atriz e o Paulo também é ⟨ator⟩.
   the Fernanda is actress and the Paulo also is actor
   Intended: ‘Fernanda is an actress and Paulo is (an actor) too.’
   (Brazilian Portuguese; Bobaljik & Zocca 2011: 142)

With regard to their tolerance for gender mismatches, these three classes can be
summarized as in Table 2:

<table>
<thead>
<tr>
<th>Class</th>
<th>MASC antecedent</th>
<th>FEM antecedent</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>doctor-class</td>
<td>✅</td>
<td>✅</td>
<td>Two-way alternating</td>
</tr>
<tr>
<td>brother-class</td>
<td>✗</td>
<td>✗</td>
<td>Non-alternating</td>
</tr>
<tr>
<td>actor-class</td>
<td>✅</td>
<td>✗</td>
<td>One-way alternating</td>
</tr>
</tbody>
</table>

We would expect that hybrid nouns in BCS pattern with one of these types. However, the additional complication with hybrid nouns is that there is evidence for the simultaneous presence of two gender features. Thus, we will try to gain some insight into their structure by testing the acceptability of gender mismatches with mismatched referents in either direction (8b)/(8c).

a. Milan mu je star-a mušterija, a Marija mu je nov-a ⟨mušt.⟩.
   Milan him is old-[F] customer and Marija him is new-[F] cust.
   ‘Milan is his old customer and Marija a new one.’

b. ? Milan mu je star-i mušterija, a Marija mu je nov-a ⟨mušt.⟩.
   Milan him is old-[M] customer and Marija him is new-[F] cust.
   ‘Milan is his old customer and Marija a new one.’

c. ? Marija mu je star-a mušterija, a Milan mu je nov-i ⟨mušt.⟩.
   Marija him is old-[F] customer and Milan him is new-[M] cust.
   ‘Marija is his old customer and Milan a new one.’
3 Experiment

The aim of the experiment was to discover whether an agreement mismatch was tolerated when masculine agreement was found either the antecedent (8b) or the ellipsis site (8c), i.e. whether the hybrid nouns under study were two-way alternating, one-way alternating, or allowed no alternation at all when the noun had natural masculine gender (indicated by the agreement on the adjective). Considering previous theories (Nunes & Zocca 2010; Bobaljik & Zocca 2011; Merchant 2014; Sudo & Spathas 2016), the (im)possibility of a mismatch should be an indicator of (i) the difference in the quality of gender features (i.e. differences in their semantics or morphosyntactic representation) and (ii) the licensing conditions on ellipsis (i.e. identity requirements between the antecedent and the ellipsis site). Finally, sentences in which both adjectives show feminine agreement, regardless of the gender of the subject, were expected to be grammatical, as the hybrid nouns in question have grammatical gender as a formal feature.

In order to verify the grammaticality of gender mismatches under NP ellipsis, we ran an online acceptability judgement study.\(^3\) The experimental design involved the factors in (9). The first factor involves the type of agreement the adjective has with a masculine subject and has two levels (grammatical agreement \(mf\) vs. natural agreement \(mm\)) (9a), which should serve as an indicator of the type of gender on the hybrid noun (grammatical vs. natural). The second factor pertains to agreement with feminine subjects and has only a single level (\(ff\), both grammatical and natural agreement) (9b). The final factor regards the position of the masculine referent and has two levels: in the first clause, or in the second clause (the one with NP ellipsis) (9c), which should indicate whether natural gender can function as an antecedent for ellipsis and whether it can be found in the ellipsis site. The \(2 \times 2 \times 1\) combination of factors in (9) yield the four experimental conditions in Table 3.

(9) **Factors** (manipulated within items)

a. AGREEMENT WITH MASCULINE SUBJECT; two levels: grammatical (\(mf\)) and natural (\(mm\))

b. AGREEMENT WITH FEMININE SUBJECT; one level: \(ff\)

c. CLAUSE; two levels: first and second

Some example test sentences for each condition are given below. Each contains two clauses coordinated by the conjunction *and* and an elided noun in the

\(^3\)For a detailed description of the design and for all the materials see https://osf.io/r3npz.
second conjunct. Sentences (10) and (12) were expected to be perceived as grammatical, while (11) and (13) were the relevant mismatching cases.

(10) Jovan je redovn-a mušterija, a Milica povremen-a ________.
    Jovan is regular-f customer and Milica occasional-f
    ‘Jovan is a regular customer and Milica an occasional one.’ MFFF

(11) Jovan je redovn-i mušterija, a Milica povremen-a ________.
    Jovan is regular-m customer and Milica occasional-f
    ‘Jovan is a regular customer and Milica an occasional one.’ MMFF

(12) Milica je povremen-a mušterija, a Jovan redovn-a ________.
    Milica is occasional-f customer and Jovan regular-f
    ‘Milica is an occasional customer and Jovan a regular one.’ FFMF

(13) Milica je povremen-a mušterija, a Jovan redovn-i ________.
    Milica is occasional-f customer and Jovan regular-m
    ‘Milica is an occasional customer and Jovan a regular one.’ FFMM

Since masculine agreement with hybrid nouns is not accepted by all speakers, a control sentence involved only masculine referents and agreement (i.e. the condition MMMM) (14).

(14) Uroš je redovn-i mušterija, a Tomislav povremen-i ________.
    Uroš is regular-m customer and Tomislav occasional-m
    ‘Uroš is a regular customer and Tomislav an occasional one.’ MMMM

Furthermore, we included the following additional controls: a grammatical baseline with feminine agreement and all feminine referents FFFF (15), and an ungrammatical baseline FMFM, involving masculine agreement with feminine referents (16).
A total of 18 controls were included, 6 per combination (all of them the same in every list, see below). There were 96 test sentences altogether, with 24 sentences per condition. All lexical items were balanced for proper names (24 male, 24 female), adjectives (48) and hybrid nouns (6). We used a Latin square design where the 96 test sentences were distributed in 4 lists, such that each list contained different items for every condition. Each participant thus saw only items from one list, i.e. 24 test items, 6 items per condition. The experiment was coded using LimeSurvey\(^4\) and run online via the LimeService platform. Sentences were presented one-by-one in a random order. Each participant saw 62 sentences (24 test items + 18 controls + 20 fillers) and was asked to give a grammaticality judgement on a 7-point Likert scale (1 = completely bad, 7 = sounds excellent) by dragging a centered slider either to the left or right to indicate their response (see Figure 1).

The experiment was performed by 164 volunteers, 131 female and 33 male, aged 16–66. Participants reportedly spoke different varieties of BCS: Bosnian (22 speakers), Croatian (5 speakers) and Serbian (136 speakers). None of the participants were paid or otherwise compensated for their participation.
Figure 2: All responses by all participants.

Figure 3: All responses by all participants according to whether the speaker liked or disliked the sentences in the MMMM condition.
4 Results

Figure 2 shows the distribution of responses under each condition from all participants for the baselines (first column) and our four experimental conditions (second and third column). The baselines show strong grammaticality effects: feminine agreement with feminine subjects was rated as grammatical, while masculine agreement was unacceptable. A u-shaped type of distribution for MMMM (masculine agreement with masculine subjects) suggests that although the majority of speakers dispreferred it, some speakers clearly did find it grammatical. With mismatching subjects, feminine agreement (FFMF and MFFF) was rated as grammatical, as shown in the second column. More gradient (un)acceptability was found for FFMM and MMFF (third column).

We compared the responses for all conditions based on whether speakers liked the MMMM combination (median rating ≥ 4) or disliked it (Figure 3). In total, 51 speakers found the MMMM combination grammatical. The overall picture shows that the distributions concerning the grammatical patterns are fundamentally the same, regardless of whether the speaker liked MMMM or not (the first two rows). However, there was in fact a difference for conditions with low acceptability scores (FFMF and MFFF), as it can be seen in the final row of Figure 3. Speakers who liked MMMM showed no clear preference or dispreference for either of the mismatching combinations – they were perceived as equally bad.

Figure 4 shows the four crucial conditions just for those speakers who rated the MMMM baseline higher than 4. We see that the patterns with feminine agreement throughout were overwhelmingly acceptable and grammatical to these speakers, while the conditions with mismatches show more variation and received comparably lower scores.

To clarify whether the differences in these responses were statistically significant, we fitted an ordinal regression model with only condition as a dependent variable, and participant and hybrid_noun as random effects (see the Appendix for further details about the model).\(^5\)

As the plot in Figure 5 shows, the factors with overlapping confidence intervals are not statistically different from each other. We see that FFFM and MFFF slightly overlap with 0, which means that they are not statistically different from the intercept (the grammatical baseline FFFF). On the other hand, FFMM and MMFF

\(^4\)https://limesurvey.org

\(^5\)Ordinal regression assumes an ordered discrete response variable. This is exactly the kind of data one obtains from grammaticality judgement tasks. In the models, gender and region did not play a role.
are statistically worse than the intercept, but not different from each other or
the ungrammatical baseline FMFM.

The conclusion we can draw from this is that gender mismatches are possible
in either direction as long as the adjectival agreement is feminine. This is shown
in (17) and (18).

(17) Two-way mismatches possible with feminine agreement
   a. Jovan je redovn-a mušterija, a Milica povremen-a (mušterija).
      Jovan is regular-F customer and Milica occasional-F customer
      ‘Jovan is a regular customer and Milica an occasional one.’  MFFF
   b. Milica je povremen-a mušterija, a Jovan redovn-a (mušterija).
      Milica is occasional-F customer and Jovan regular-F customer
      ‘Milica is an occasional customer and Jovan a regular one.’  FFMF

(18) No mismatch possible with masculine agreement
   a. * Milica je povremen-a mušterija, a Jovan redovn-i (mušterija).
      Milica is occasional-F customer and Jovan regular-M customer
      ‘Milica is an occasional customer and Jovan a regular one.’  FFMM
   b. * Jovan je redovn-i mušterija, a Milica povremen-a (mušterija).
      Jovan is regular-M customer and Milica occasional-F customer
      ‘Jovan is a regular customer and Milica an occasional one.’  MMFF

Figure 4: Responses by participants who liked MMMM (median rating ≥ 4)
Thus, with regard to the noun classes in Table 2, our hybrid nouns behave like nouns of the two-way alternating *actor*-class when there is agreement in grammatical gender (feminine), but they behave like non-alternating nouns of the *brother*-class if at least one of them bears natural gender (masculine).

5 Analysis

First, let us assume that the identity requirement for elided material involves Merchant’s (2001) e-*givenness* (i.e. mutual entailment), as defined in (19), where existential (∃)-type shifting is “a type-shifting operation that raises the expressions of type $t$ and existentially binds unfilled arguments” while F-closure of $\alpha$ “is the result of replacing F-marked parts of $\alpha$ with ∃-bound variables of the appropriate type (modulo ∃-type shifting)” (Merchant 2001: 14):

\begin{equation}
\text{e-*givenness} \quad \text{(Merchant 2001: 26)}
\end{equation}

An expression $E$ counts as e-*given* iff $E$ has a salient antecedent $A$ and, modulo ∃-type shifting,

(i) $A$ entails F-clo($E$), and

(ii) $E$ entails F-clo($A$).
This condition requires that mutual entailment holds between the antecedent and the ellipsis site. This prevents semantically-equivalent, non-matching ellipsis sites (20b) Merchant (2001: 27).

(20)  a. * Abby called Ben an idiot after Mary did ⟨call Ben an idiot⟩.
      (\exists x. x called Ben an idiot ↔ \exists x. x called Ben an idiot)

      b. # Abby called Ben an idiot after Mary did ⟨insult Ben⟩.
      (\exists x. x called Ben an idiot ↔ \exists x. x insulted Ben)

Following Cooper (1983), it is often assumed that (natural) gender features can introduce presuppositions (also see Sauerland 2003; 2008; Heim 2008; Kratzer 2009; Spathas 2010; Sudo 2012). In Greek, non-alternating nouns of the brother-class have been claimed to contain a presupposition about gender of the referent (21) (Merchant 2014: 19, Sudo & Spathas 2016: 715).

(21)  a. \text{\textit{adherfos}} = \lambda x_\text{e} : \text{\textit{male}}(x). \text{\textit{sibling}}(x)

      b. \text{\textit{adherfi}} = \lambda x_\text{e} : \text{\textit{female}}(x). \text{\textit{sibling}}(x)

(22)  a. * O the Petros ine kalos adherfos, ala i Maria ine mia kakia
      the Petros is good.m brother but the Maria is a.f bad.f
      (adherfi).
      sister
      Intended: ‘Petros is a good brother, but Maria is a bad one (sister).’

      b. * I the Maria ine kali adherfi, ala o Petroso ine es kakos
      the Maria is good.f sister but the Petros is a.m bad.m
      (adherfos).
      brother
      Intended: ‘Petros is a good brother, but Maria is a bad one (sister).’
      (Greek; Merchant 2014: 12)

The elided and antecedent noun have conflicting gender presuppositions, not mutually-entailing:

(23)  \exists x : \text{\textit{male}}(x). \text{\textit{sibling}}(x) ↔ \exists x : \text{\textit{female}}(x). \text{\textit{sibling}}(x)

In the analysis of two-way alternating “epicene” nouns, however, it is often assumed that they do not contain any lexical presuppositions about gender (24), and thus ellipsis is licensed (26).

(24)  \text{\textit{jatros}} = \lambda x_\text{e} . \text{\textit{doctor}}(x)
Andrew Murphy, Zorica Puškar & Matías Guzmán Naranjo

(25)  
  a. O Petros ine kalos jatros, ala i Maria ine mia kakia (jatros).  
      the Petros is good.m doctor but the Maria is a.f bad.f doctor  
      ‘Petros is a good doctor, but Maria is a bad one.’  
  b. I Maria ine kali jatros, ala o Petros ine enas kakos (jatros).  
      the Maria is good.f doctor but the Petros is a.m bad.m doctor  
      ‘Maria is a good doctor, but Petros is a bad one.’

      (Greek; Merchant 2014: 15)

(26)  \[ \exists x . \text{DOCTOR}(x) \leftrightarrow \exists x . \text{DOCTOR}(x) \]

If we adopt a similar approach for hybrid nouns in BCS, then hybrid nouns agreeing in grammatical gender (feminine) do not contain any presupposition about gender, while the hybrid nouns that agree in natural gender (masculine) should have an additional gender presupposition. Assuming that the grammatical feminine gender of hybrid nouns does not contribute any gender presupposition, this would make it compatible with male and female referents:

(27)  \[ [n_{[f]}] = \lambda P \lambda x . P(x) \]

For masculine-agreeing hybrid nouns, let us assume that the denotation of natural gender is a partial identity function restricting the set of customers to the set of male customers (Cooper 1983).

(28)  \[ [n_{[m]}] = \lambda P \lambda x : \text{male}(x) . P(x) \]

The introduction of a gender presupposition with masculine agreeing hybrid nouns makes them incompatible with female referents.6

(29)  
  a. Marija nam je nov-a mušterija.  
      Marija us is new-f customer  
      ‘Marija is our new customer.’  
  b. * Marija nam je nov-i mušterija.  
      Marija us is new-m customer  
      ‘Marija is our new customer.’

(30)  \([\text{novi mušterija}] = \lambda x . \text{CUSTOMER}(x)\), defined only if \(x\) is male

a.  \([29a] = \text{CUSTOMER}($\text{MARIJA}$)

---

6While other theories rule out such examples based on competition with the feminine agreeing form (e.g. Maximize Presupposition; Bobaljik & Zocca 2011: 148f. or Principle of Gender Competition; Sudo & Spathas 2016: 722), we argue that the syntactic presence of both features is necessary based on instances of mixed agreement, such as (3).
Returning to gender mismatches under ellipsis, in an example such as (31), involving feminine agreement in both clauses, both instances of \textit{mušterija} will lack natural gender feature and the corresponding presupposition.

(31) Milica je povremen-a mušterija, a Jovan redovn-a (mušterija).

‘Milica is occasional\-F customer and Jovan regular\-F customer.’

In order to analyze the ellipsis patterns, we adopt the assumptions of Distributed Morphology that nouns are built up from a category neutral root and a head \( n \) that categorizes this root as nominal (Halle & Marantz 1993; Harley & Noyer 1999; Kihm 2005; Acquaviva 2009; Kramer 2015). Following Kramer (2015), we will treat gender for now as a feature introduced by \( n \) (although see below for more detail about the different possibilities of simultaneous separate structural encoding of natural and grammatical gender on hybrid nouns). We assume further that number features of nouns are introduced on a NumP. These assumptions yield the structure for (31) as given in (32), where ellipsis is triggered by an \([E]\) feature on Num (e.g. Merchant 2014; Saab & Lipták 2016; Saab 2019).

\begin{center}
\begin{tikzpicture}[level distance=1cm, level 1/.style={sibling distance=4cm}, level 2/.style={sibling distance=2cm}, level 3/.style={sibling distance=1cm}]

\node{\textit{DP} \ldots}
    child{node{\textit{DP} \ldots}}
    child{node{\textit{A} povremen-a NumP}
        child{node{\textit{A} redovn-a NumP}
            child{node{\textit{NumP} \ldots}}
        }
    }

\end{tikzpicture}
\end{center}

Importantly, from the point of view of the e-GIVENness condition in (19), mutual entailment is trivially satisfied since the elided material is identical.
(33) \[
\begin{array}{c}
P \quad \muşterija \\
\exists x. \text{CUSTOMER}(x)
\end{array} \leftrightarrow \begin{array}{c}
P \quad \muşterija \\
\exists x. \text{CUSTOMER}(x)
\end{array}
\]

However, as soon as we have masculine agreement on one of the conjuncts, we necessarily have the relevant natural gender feature \([m]\) of the referent, making the ellipsis unacceptable (34). The relevant structure, demonstrating the lack of feature identity, is given in (35).

(34) *Milica je povremen-a muşterija, a Jovan redovn-i (muşterija). 
Milica is occasional-f customer and Jovan regular-m customer 
'Milica is an occasional customer and Jovan a regular one.'

(35) **Antecedent:**

Recall that the masculine feature also introduces the presupposition that the referent is male. If there is no corresponding feature in the antecedent, then e-givenness is violated because there being a customer does not entail there being a male customer:

(36) \[
\begin{array}{c}
P \quad \muşterija \\
\exists x. \text{CUSTOMER}(x)
\end{array} \rightarrow \begin{array}{c}
P \quad \muşterija \\
\exists x: \text{MALE}(x). \text{CUSTOMER}(x)
\end{array}
\]

The same situation holds if masculine agreement obtains in the antecedent:
Since mutual entailment is required, the existence of masculine gender at only one of the conjuncts results in ungrammaticality, since the e-givenness requirement is not met.

This accounts for why mismatches in referent gender are not tolerated if the adjective agrees in masculine in one conjunct only. As we expect, if we have two masculine referents (39), then mutual entailment is restored (40).

Exactly why masculine agreement with hybrid nouns (39) is not possible for all speakers is an open issue, and we suggest it could be due to not all speakers having the variant of \( n \) containing the additional \([M]\) feature. We leave further examination of interspeaker variation to future research.

5.1 The encoding of natural and grammatical gender features

Since the nouns addressed in this paper have the possibility to simultaneously encode both the grammatical feminine and the natural masculine gender (as illustrated by (3), see also Wechsler & Zlatić 2003; Despić 2017; Puškar 2017), a question that remains open is where exactly these features are encoded in the DP structure.
Some accounts (Matushansky 2013; Pesetsky 2013; Landau 2016) assume grammatical gender to be encoded low in the noun’s structure, as a property related to the nominal stem. Natural gender is optionally introduced on a higher functional projection. Under this approach, we would treat the grammatical feminine gender of our hybrid nouns as a property of $n$, while natural gender would be introduced at a higher functional projection (e.g. GenP, cf. Picallo 1991). The lower gender would not introduce any gender presuppositions, while the denotation of the gender on Gen would be a partial identity function restricting the set of customers to the set of male customers (Cooper 1983). If the male-referring hybrid noun triggers feminine agreement, adjectival concord then targets the grammatical gender feature on $n$ (41).

\[
\begin{array}{c}
\text{(41)} \\
\end{array}
\]

For masculine-agreeing hybrid nouns, the closest target for Agree will be the higher masculine gender (42).

\[
\begin{array}{c}
\text{(42)} \\
\end{array}
\]
Ellipsis would be licensed if neither the antecedent nor the elided noun project the GenP, or if both of them do. The existence of GenP and the masculine feature in either the antecedent or the ellipsis site would lead to a lack of mutual entailment and the concomitant impossibility of ellipsis, in the manner proposed above.

Another theoretical option would be to make the GenP the locus of grammatical gender, and the \( n \) of the natural one for the hybrid nouns of this particular type (see Puškar 2017; 2018). A hybrid noun with no natural gender would be represented as (43), while the noun with the natural gender feature would have the structure in (44). Under this approach, the natural gender feature of \( n \) would have a more complex syntactic representation than the grammatical one. The gender probe is relativized towards the more complex gender. If this gender is present on the \( n \), it will be the preferred goal for Agree (44). If it is absent, Agree would copy the higher grammatical gender (43) (see Puškar 2017 for further detail).

If this analysis were to be adopted, the ungrammatical sentences would be ruled out by prohibiting any mismatches between the features of antecedent and those of the ellipsis site (cf. Merchant 2013).

To sum up, both types of approaches to the structural position of gender features would in principle be compatible with the results of our experiment. Future
research should then be tasked with teasing apart the two and defining the exact locus of the natural and grammatical gender features. However, what the results undoubtedly reveal is the necessity to represent the two types of features separately, as well as that they differ in quality, such that natural gender has an additional meaning component.

6 Conclusion

This paper has presented new experimental data from NP ellipsis showing that hybrid nouns in BCS show a split behaviour with regard to gender ellipsis: if they agree in feminine gender, then mismatches in referent gender are permitted for either the antecedent or elided noun. However, masculine agreement in either conjunct blocks gender mismatches. We have linked this to the optional presence of a natural [m] gender feature which represents a target for adjectival concord and introduces a gender presupposition. It is this gender presupposition that destroys the mutual entailment relation required by Merchant’s (2001) e-givenness requirement on ellipsis licensing. Consequently, this study suggest that natural masculine gender is syntactically absent when the adjective agrees in grammatical gender.

M masculine  SG singular
PL plural

Acknowledgements

We would like to thank Ana Bosnić and Joanna Zaleska for the help with the experimental design and coding, as well as Boban Arsenijević, Jelena Stojković, Andrew Nevins and the audience of FDSL 12 for the valuable comments and feedback.

Appendix

We use an ordinal Bayesian regression model with the package MCMCglmm (Hadfield 2010) in R (R Core Team 2016). We used non-informative priors (an inverse
gamma with V=1 and nu=0.002). Table 4 presents the posterior mean estimates, the confidence intervals and equivalent of a Bayesian p value. The corresponding posterior estimates of the random effects can be are shown in Table 5.
